

# Growth of Functions

This section starts off with the main ideas near the end of section 7.7 but goes on a bit further.

The interest in this section is how functions behave as  $x \rightarrow \infty$ . There are lots of functions that go to infinity:  $x$ ,  $x^2$ ,  $e^x$ ,  $x^x$ ,  $\ln(x)$ ,  $\ln(x)^2$  and so on. The question we will focus on in this section is: *How fast do these functions go to infinity? Do some of them go to infinity “faster” than others?*

Let us start with a definition:

We say that a function  $g(x)$  **grows faster** than a function  $f(x)$ , if:

$$\lim_{x \rightarrow \infty} \frac{g(x)}{f(x)} = \infty$$

We denote this by

$$f(x) \ll g(x)$$

We could also instead check that:

$$\lim_{x \rightarrow \infty} \frac{f(x)}{g(x)} = 0$$

Notice that a lot of those quotients will end up being indeterminate forms of the type  $\frac{\infty}{\infty}$ .

For example,  $2x$  is not considered to grow faster than  $x$ , because  $\lim_{x \rightarrow \infty} \frac{2x}{x} = 2 \neq \infty$ . On the other hand,  $x^2$  does grow faster than  $x$ .

Here are some facts about the relative growth of functions:

$$\begin{aligned} x^n &\ll x^m \text{ when } m > n \\ x^n &\ll e^x \ll e^{2x} \ll e^{x^n} \text{ for all } n \\ \ln(x)^n &\ll x^\alpha \text{ for all } n, \alpha > 0 \end{aligned}$$

Let us demonstrate these various assertions. We start with the first, which is easy to see by looking at  $\lim_{x \rightarrow \infty} \frac{x^m}{x^n} = \lim_{x \rightarrow \infty} x^{m-n} = \infty$ .

The limits that compare the various exponentials follow from the formula:

$$\frac{e^{f(x)}}{e^{g(x)}} = e^{f(x)-g(x)}$$

So as long as  $\lim_{x \rightarrow \infty} f(x) - g(x) = \infty$ , then  $e^{f(x)} \gg e^{g(x)}$ . This helps us show for example that  $e^x \ll e^{2x} \ll e^{x^2} \ll e^{x^3}$  and so on.

The hardest comparison is between  $x^n$  and  $e^x$ . Let us work on that now:

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^n}$$

As long as  $n > 0$ , we have a  $\frac{\infty}{\infty}$  form, and we can apply L'Hopital's rule to get:

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^n} = \lim_{x \rightarrow \infty} \frac{e^x}{n x^{n-1}}$$

This is again an indeterminate form, but where the  $x^n$  power is now of lower degree, but the  $e^x$  has remained unchanged. Continuing this way, we will eventually get to a point where we have  $e^x$  on the numerator, and a number  $(n(n-1)(n-2) \cdots 2 \cdot 1)$  in the denominator. This limit would then be infinity.

Let us try out some of the remaining comparisons, for instance comparing different exponentials:

$$\lim_{x \rightarrow \infty} \frac{e^{f(x)}}{e^{g(x)}} = e^{\lim_{x \rightarrow \infty} f(x) - g(x)}$$

So  $e^{f(x)} \ll e^{g(x)}$  if  $\lim_{x \rightarrow \infty} f(x) - g(x) = -\infty$  and  $e^{f(x)} \gg e^{g(x)}$  if  $\lim_{x \rightarrow \infty} f(x) - g(x) = +\infty$ .

Use this to compare  $e^x$ ,  $e^{2x}$  and  $e^{x^2}$ .

Finally, for the logarithm, we use L'Hopital's rule:

$$\lim_{x \rightarrow \infty} \frac{\ln(x)}{x^\alpha} = \lim_{x \rightarrow \infty} \frac{1/x}{\alpha x^{\alpha-1}} = \lim_{x \rightarrow \infty} \frac{1}{\alpha x^\alpha} = 0$$

as long as  $\alpha > 0$ .
